

String Slicing

In this lesson, we'll understand what slicing is and how it can be applied to strings.

We'll cover the following

- Definition
- Slicing with a Step
- Reverse Slicing
- Partial Slicing

Definition

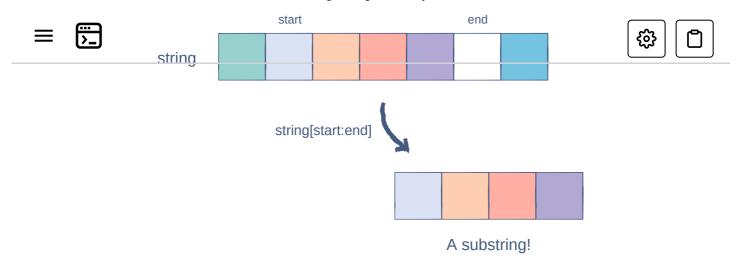

Slicing is the process of obtaining a portion (substring) of a string by using its indices.

Given a string, we can use the following template to slice it and obtain a substring:

string[start:end]

- start is the index from where we want the substring to start.
- end is the index where we want our substring to end.

The character at the end index in the string, will not be included in the substring obtained through this method.

Let's look at a few examples:

```
1 my_string = "This is MY string!"
2 print(my_string[0:4]) # From the start till back
3 print(my_string[1:7])
4 print(my_string[8:len(my_string)]) # From the
5
```

Slicing with a Step

Until now, we've used slicing to obtain a contiguous piece of a string, i.e., all the characters from the starting index to before the ending index are retrieved.

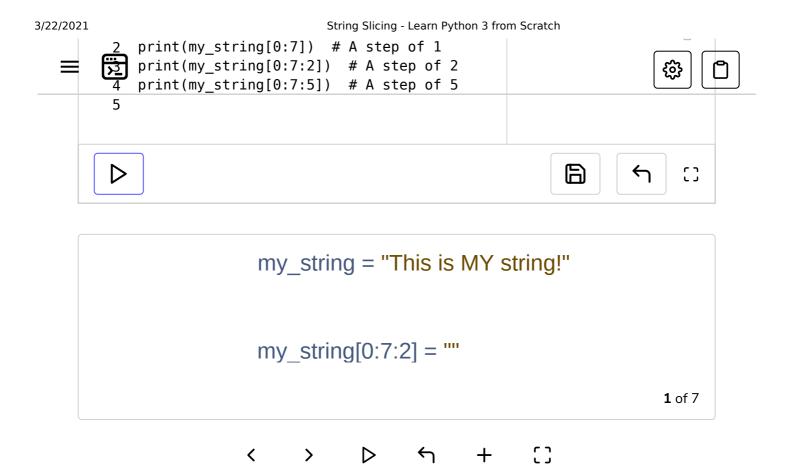

However, we can define a **step** through which we can skip characters in the string. The default step is 1, so we iterate through the string one character at a time.

The step is defined after the end index:

```
string[start:end:step]
```

Let's see how this works:

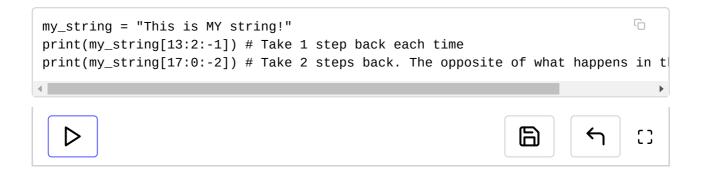

```
1 my_string = "This is MY string!"
```

Reverse Slicing

Strings can also be sliced to return a reversed substring. In this case, we would need to switch the order of the start and end indices.

A negative step must also be provided:

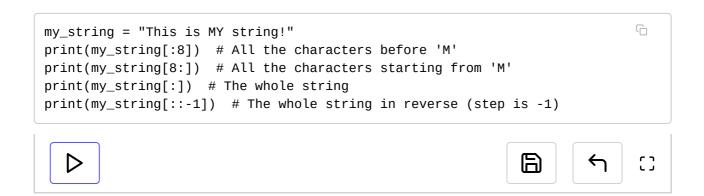

Partial Slicing

One thing to note is that specifying the start and end indices is **optional**.

= If the index. If is not provided, the substring will have all the characters with the end index.

If end is not provided, the substring will begin from the start index and go all the way to the end.

Let's see this in action:

That's pretty much all we need to know about string slicing. Play around with the strings above to get a better understanding of how slicing works.

In the next lesson, we'll understand the purpose of operators in Python.
